

1. Create a calculated column TotalPrice using Quantity and Unit Price

-> $\text{TotalPrice} = \text{Amazon_Store_Sales}[\text{Quantity}] * \text{Amazon_Store_Sales}[\text{UnitPrice}]$

2. Create a calculated column DiscountedPrice

-> $\text{DiscountedPrice} = \text{Amazon_Store_Sales}[\text{TotalPrice}] * (1 - \text{Amazon_Store_Sales}[\text{Discount}])$

3. Create a measure Average Order Value (AOV).

-> $\text{AOV} = \text{DIVIDE}(\text{SUM}(\text{Amazon_Store_Sales}[\text{SalesAmount}]), \text{DISTINCTCOUNT}(\text{Amazon_Store_Sales}[\text{OrderID}]))$

Dataset Result

- Total Sales = 1,258,041.61
- Total Orders = 500
- $\text{AOV} \approx 2,516.08$

4. Using DAX, create a measure that calculates cumulative Year-to-Date (YTD) Sales based on the Order Date

-> $\text{YTD Sales} = \text{TOTALYTD}(\text{SUM}(\text{Amazon_Store_Sales}[\text{SalesAmount}]), \text{Amazon_Store_Sales}[\text{OrderDate}])$

5. Using DAX, create a measure to rank each product according to its Total Sales, with the highest-selling product ranked first

-> Total sales measure

Total Sales =
 $\text{SUM}(\text{Amazon_Store_Sales}[\text{SalesAmount}])$

Then create the ranking measure:

Product Rank =

```
RANKX(  
    ALL(Amazon_Store_Sales[ProductID]),  
    [Total Sales],  
    ,  
    DESC,  
    DENSE  
)
```

6. Create a calculated column classifying orders as “High Value” if sales > 2000, else “Low Value”.

-> Order Category =

```
IF(  
    Amazon_Store_Sales[SalesAmount] > 2000,  
    "High Value",  
    "Low Value"  
)
```

7. Create a measure to calculate total sales from the Online channel only.

-> Online Sales =

```
CALCULATE(  
    SUM(Amazon_Store_Sales[SalesAmount]),  
    Amazon_Store_Sales[SalesChannel] = "Online"  
)
```

8. Create a measure called "Date Difference" that calculates the number of days between the latest Order Date and today's date using the DATEDIFF function.

-> Date Difference =

```
DATEDIFF(  
    MAX(Amazon_Store_Sales[OrderDate]),  
    TODAY(),  
    DAY  
)
```
